points of the beam path.

To this end we have developed an algorithm program, written in Matlab code, which perform a closed loop process via RS232 protocol. It combines three subsystems: the source is a He-Ne laser [1], the actuator is a motorized ultrasonic mirror mount [2] and the sensor is a Color Camera [3]. The signal of the position of the beam is detected on a XY Cartesian plane; this information processed by the algorithm which will activate the compensation motion of the actuators. The accuracy could reach sub millimeters level.

Introduction

One of the most critical element of any laser system is the alignment of the laser beam throughout the whole beam path until the desired target. Once the alignment has been achieved, the system is naturally subject to a number of perturbations which can cause deviations from desired path (for example temperature oscillations). To re-establish the correct operation of the laser system a re-alignment is necessary. This could be manually operated, but the process is time consuming and not efficient. The alternative is to automatically operate the alignment via motorized mirror mounts, typically located at key

Before doing any experiments, it's critical to thoroughly understand laser safety procedures and have the necessary safety eyewear. The red tracking and motion control of mirror mount are important topics in robotics and automation that are

The algorithm controlling mirror mount was written in Matlab script. The own Gui-interface and program are developed for OptoSigma's Motorized mirror mounts, this program permit to connect to a device through RS232 serial and sending a string commands. A camera attached to a PC takes continuous snapshots of particular object (a red object in this case), detects the presence and position of red object using color detection, and tracks the movement of the object in subsequent snapshots[2]. The red object is quantified and used to determine

Conclusion and perspective

control of the motion of the mirror mount.

The Matlab algorithm was able to successfully detect the red laser object and track its movement in subsequently acquired video and move the orienting mirror to reach the setting desired target compensate the error in order of 2mm with max-speed of an ultrasonic actuators. The future works will concern the control with two mirror mounts with resolving beam error degree via
